ASHRAE Illinois Research Night, Lombard IL

ASHRAE Chicago Chapter

Executive Summary

Developing analysis methodologies by which the time period for field monitoring of energy use in buildings can be reduced to less than a whole year while satisfying preset accuracy levels of annual energy performance verification.

Cost effective alternative for ESCO's, and energy professionals.

Application areas of the methodology are: Detailed Audits, Green Building Performance Verification, and Verification of Post-Retrofit Claims using Pre-Post Monitored Data.

Executive Summary

The research revealed the following:

- 1- Two weeks of hourly monitored data can be adequate for producing accurate long-term whole building energy predictions, provided the monitoring is taken at a correct time.
- 2- Adding more data to the regression model (extending the length of the short-term monitoring period) can, contrary to intuition, make the predictive model much poorer.
- 3-The proper monitoring period is highly dependent on the time at which the data is taken, with the best time to collect data being during the swing seasons.

Hourly Hybrid Multivariate Change Point Models Tested

Hourly Hybrid Multivariate Change Point Model Flowchart

Large Office Building located in Chicago - WBE

Large Office Building located in Chicago - WBE

Large Office Building located in Chicago - WBE

$$Y = A + B(DBT - cp)^+$$

$$WBE_{(kWh/day)} = 13,393 + 259.7(DBT_{(F)} - 43.8)^+$$

$$\text{Hourly Residuals} = Y - \left(\frac{B}{24}\right)(DBT - cp)^+$$

$$\text{Hourly Residuals} = WBE_{(kWh/h)} - \left(\frac{259.7}{24}\right)(DBT_{(F)} - 43.8)^+$$

$$\text{Hourly Residuals} = D + E(LTEQ)$$

$$\text{Hourly Residuals} = 17 + 1.2(LTEQ_{(kWh/h)})$$

$$\text{Final Model: } Y = D + \left(\frac{B}{24}\right)(DBT - cp)^+ + E(LTEQ)$$

$$\text{Final Model: } WBE_{(kWh/h)} = 17 + \left(\frac{259.7}{24}\right)(DBT_{(F)} - 43.8)^+ + 1.2(LTEQ_{(kWh/h)})$$

Year Long Utility Bills Combined with a Short Data Set

- At hourly scale, two weeks was found to be an acceptable monitoring length. Many suitable models came from swing seasons (April and October)
- Good flexibility in monitoring time (1.2 million models)
 - WBE, median NMBE $\approx 1.6\%$
 - CHW, median NMBE $\approx 5.8\%$
 - HW, median NMBE $\approx 4.5\%$
 - ASHRAE Guideline 14 suggests $\pm 10\%$

Year Long Utility Bills Alone

- Coefficient of Variation (CV) was greater without the short term data set (10 – 15% extra CV compared to hybrid)
- Fairly accurate energy estimate at both monthly and annual timescales

Guidance to Energy Professionals

Uncertainty Methods (Across Climates)

Uncertainty Methods (Across Building Sectors)

Conclusions

- Little to no improvement was found introducing a time lag in the variables used in the hourly models.
- Predictions for cooling energy use were better in warmer climates, and predictions for heating energy use were better in cooler climates.

Conclusions

- For robust models, the temperature change point that exists in many building energy profiles needs to be accounted for.
- Modeling with only utility bills data provided a fairly accurate estimate of the long-term energy use patterns of buildings. A minimum amount of monitoring, however, can improve the results.

Conclusions

- In general, the swing seasons (April and October) have been found to be the best time to complete short term monitoring (1 month or less).
- Extending the monitoring period to cover extreme weather would result in poorer predictions, compared with using much shorter periods taken from the swing seasons.

Conclusions

- The most important factor in the predictive ability of the models has been the closeness of the data set's mean dry bulb temperature to the annual mean, and also that of the data set's temperature range to the annual range.
- The Hourly Hybrid Multivariate Change Point Model (with utility bills) has been found to be the most effective model for annual building energy prediction using data sets covering 1 month or less.
